Agenda

1. Introduction
2. Strategic Framework
3. Parameter Valuations
4. Case Study – Results and Discussion
5. Conclusions

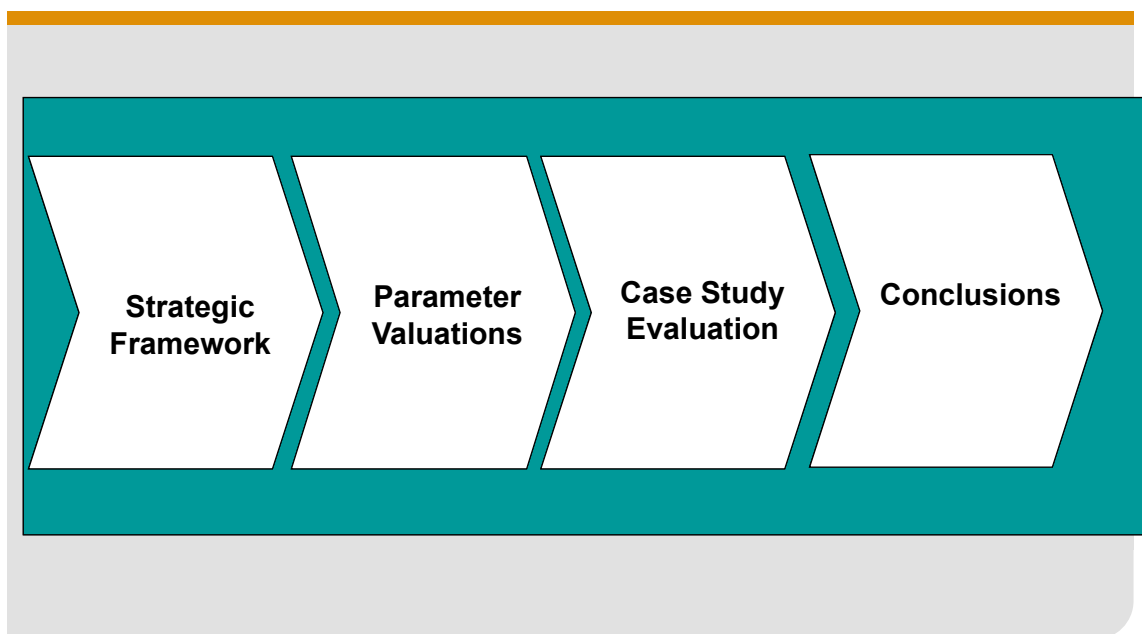

This paper compares international urban rail CBA methodologies

- **This is background research for a PhD project examining new approaches in rail benefit assessment (notably agglomeration economies)**
- **Aim is to seek out alternative approaches**
 - Strategic Level (high level approaches)
 - Tactical Level (parameter valuations)
- **Differences are illustrated via a comparator evaluation project**

Across 12 countries using published sources

- **12 countries**
 - Australia, the US, the UK, Canada, New Zealand, Germany, Holland, France, Japan, Hong Kong, the Republic of Korea and Singapore
- **Sources – published evidence (including national guidelines and research papers) and communication with the relevant authorities**
- **Proviso**
 - national guidelines – many localised differences in approaches within countries
 - All aspects of methodology not fully documented

It is structured as follows:

Agenda

1. Introduction
2. Strategic Framework
3. Parameter Valuations
4. Case Study – Results and Discussion
5. Conclusions

All CBA's use multi-criteria analysis

Role of CBA

- **CBA is one key component of the multi-criteria analysis (MCA) for project evaluation adopted by all countries**
- **There is some variation in how CBA is used**
- **Project evaluation is usually supplemented by other specialised study e.g. Environmental Impact Statement**
- **MCA results are usually summarised in a tabular form – e.g. the Australian Appraisal Summary Table**

Cost components are similar

Cost Components

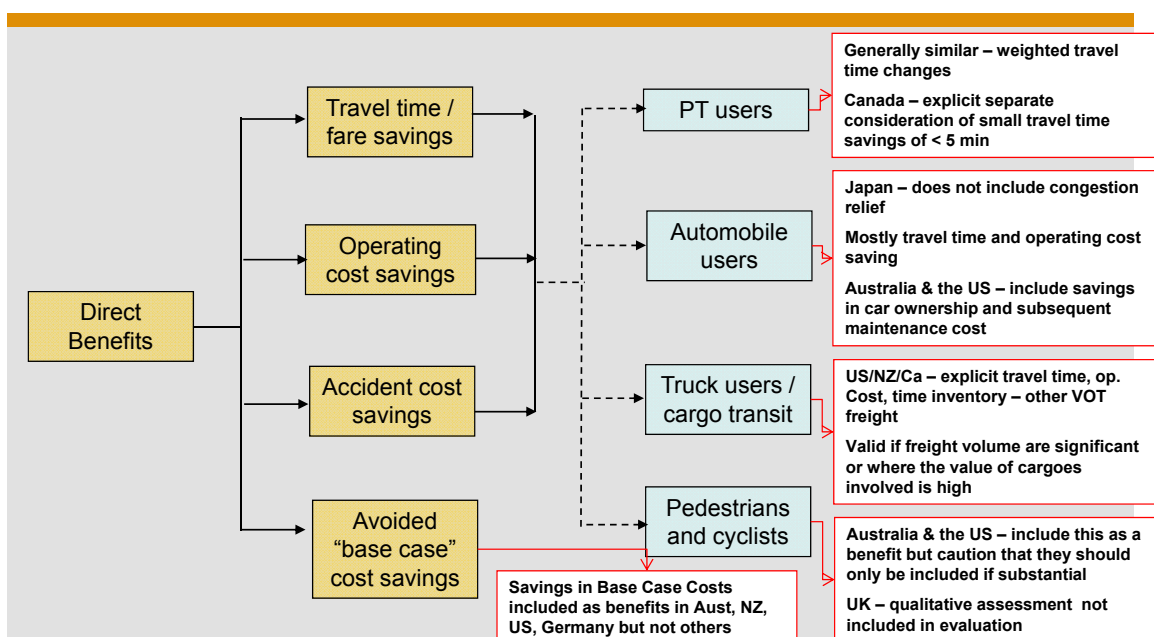

- **All countries include capital, operating and maintenance costs in their CBA**
- **Land cost – considered as part of project cost; valued at market value**
- **Cost of corresponding mitigation measures are usually included in project cost**
- **Residual value of assets**
 - treated as a negative cost in the last appraisal year or as an initiative benefit
 - the UK and the Netherlands specify a criterion for its inclusion (project less than 60 and 100 years)
 - US, NZ Germany, Singapore have no residual value

There is more variation in benefit assessment...

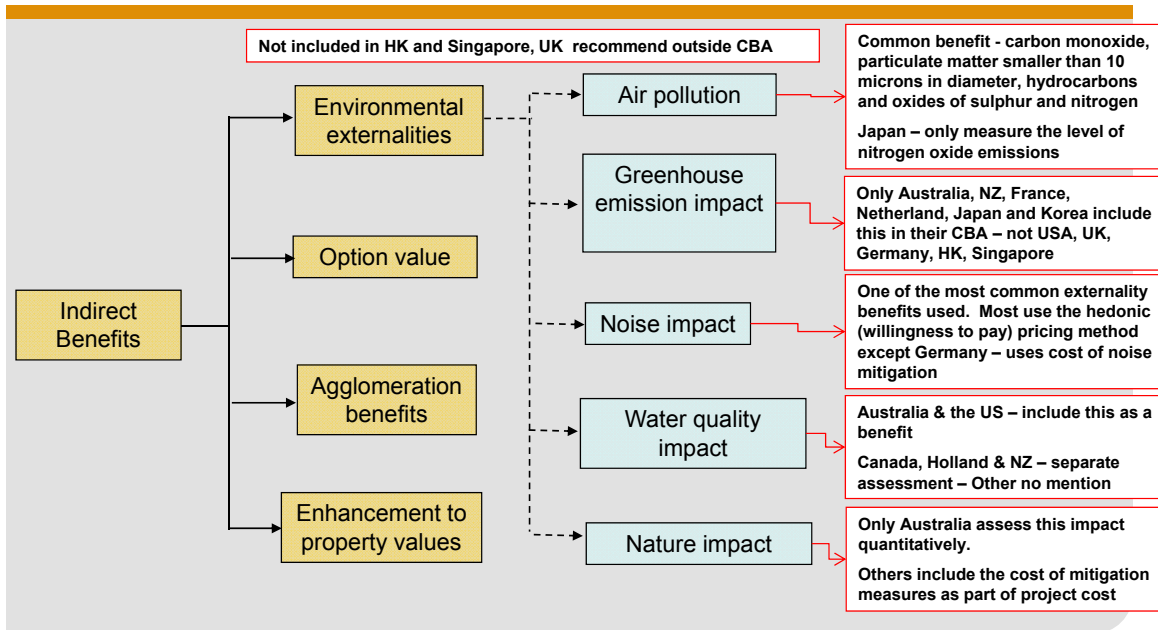

Benefit Assessment

- **Benefits are generally classified as Direct and Indirect benefits**
 - Direct benefits – benefits associated with the activity of travel itself and its effects on user
 - Indirect benefits – benefits that are generated over and above the direct benefits

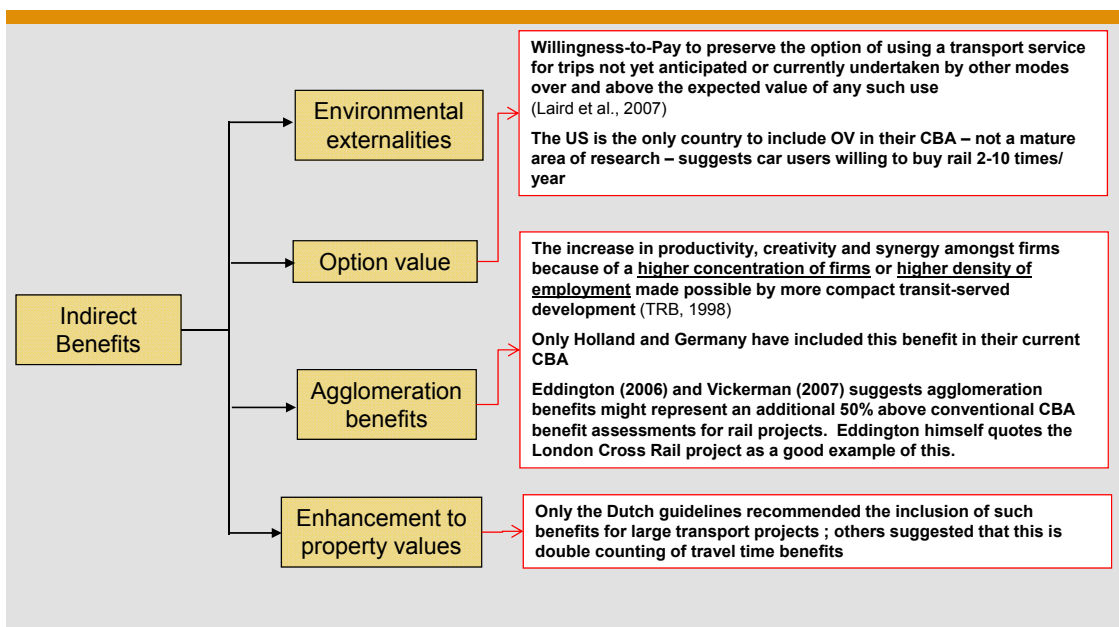

...Direct benefits...

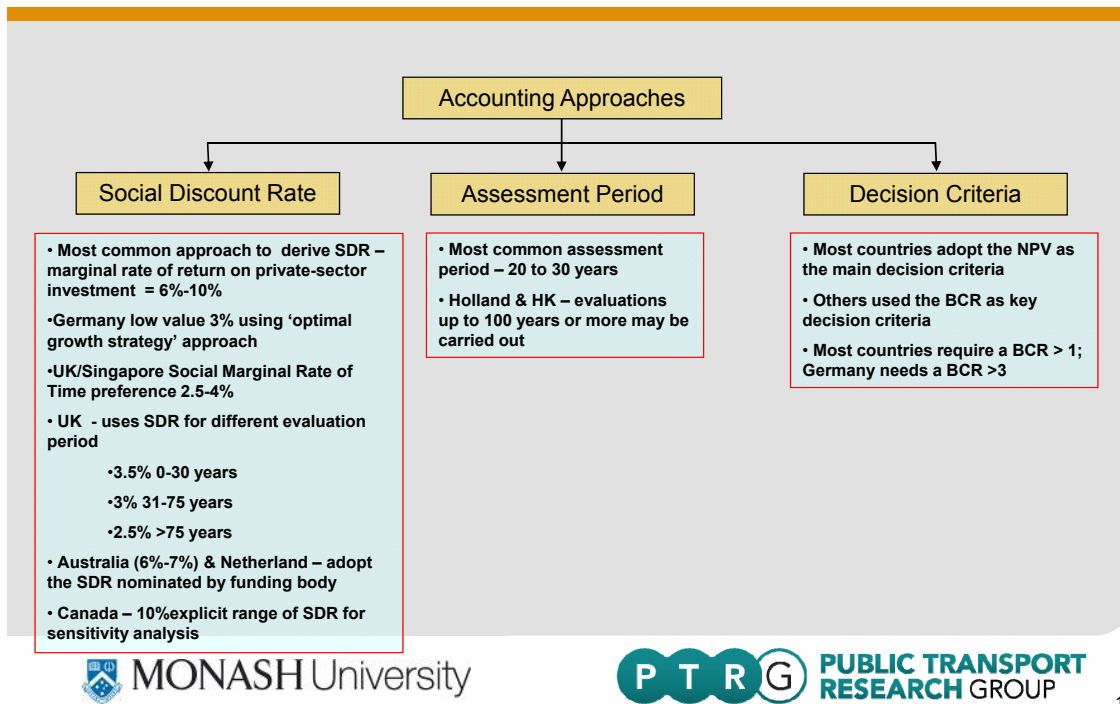

...In-direct benefits...

...In-direct benefits...

...and accounting approaches

14

Parameter values were adjusted to make comparisons valid across currencies/time

- **Examined in 3 broad categories:**
 - Value of Private Time (VOT),
 - accident costs; and
 - values of externalities
- **To aid comparison, parameter values are updated by :**
 - using the average wage increment of each country between the date the value was captured and Year 2006; and
 - converted to A\$2006 values based on ARB's exchange rate

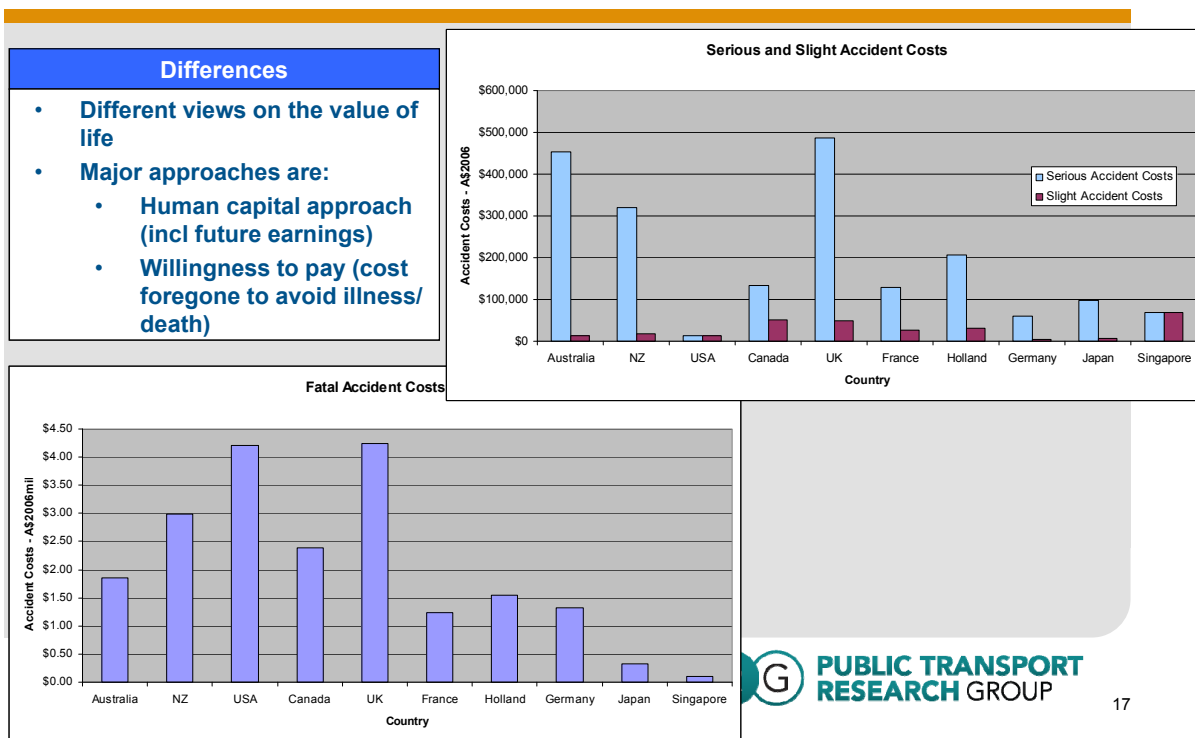

VOT varies \$5-\$15 based on incomes – PT/car valuations are usually the same

Differences

- Wage rates (30-50%)
- Work to Non-Work Hour Ratios
- Tax Rates

Accident rates show much variation

Externality use and valuation vary with estimation methods

- Different countries have derived very different monetary values for environmental impacts due to different methods employed and costing principles (Nash, 1997).**
- For example**
 - Noise Pollution
 - > US = A\$0.00115 / veh-km
 - > Australia = A\$0.00800 / veh-km
 - Greenhouse Emissions
 - > France = A\$0.0079 / pax-km
 - > Netherlands = A\$0.0064 / veh-km
 - > Australia = A\$0.0032 / veh-km
- Most guidelines advised that unit costs to be used with caution and to carry out a detailed impact assessment if necessary**

Agenda

1. Introduction
2. Strategic Framework
3. Parameter Valuations
- 4. Case Study – Results and Discussion**
5. Conclusions

The case study examined a rail electrification project

- The project is evaluated using the CBA framework and parameter values of each country
- All appraisals are carried out in A\$2006
- Capital and operating cost is assumed to be the same for all countries
- An average VOC of A\$0.16/km is assumed for countries where no VOC information is available
- For Canada and Holland – air pollution, greenhouse effect and noise pollution are included
- For US – OV benefit is estimated based information from TRB (2002) (small)
- For Germany and Holland – Agglomeration benefits is assumed to be 50% of the direct benefits as suggested by Eddington (2006) and Vickerman (2007)
- The corresponding Australian rates are applied where no parameter values are available.

UK had highest cost – longer evaluation period & lower DR's increase costs

Agglomeration impact, high VOT, evaluation period and low DR generate high benefits

Overall the project is positive in only 5 (4) of the 12 countries

Agenda

1. Introduction
2. Strategic Framework
3. Parameter Valuations
4. Case Study – Results and Discussion
5. Conclusions

Key Findings

- **Aim: comparative international review of rail CBA**
- **Similarities:**
 - Framework (MCA), Handling of costs
- **Differences**
 - Direct/Indirect Benefits
 - VoT and agglomeration benefits significant
 - Length of evaluation period and discount rate significant
- **Comparative case study**
 - Aust, US, UK, Holland BCR>1
 - NZ, Canada, France, Japan, HK, Singapore BCR<1
 - Germany BCR = 1.86 below 3 threshold
